# Edge detection

- **Goal:** Identify sudden changes (discontinuities) in an image
  - Intuitively, most semantic and shape information from the image can be encoded in the edges
  - More compact than pixels
- **Ideal:** artist's line drawing (but artist is also using object-level knowledge)

Source: D. Lowe

# Origin of Edges

- Edges are caused by a variety of factors

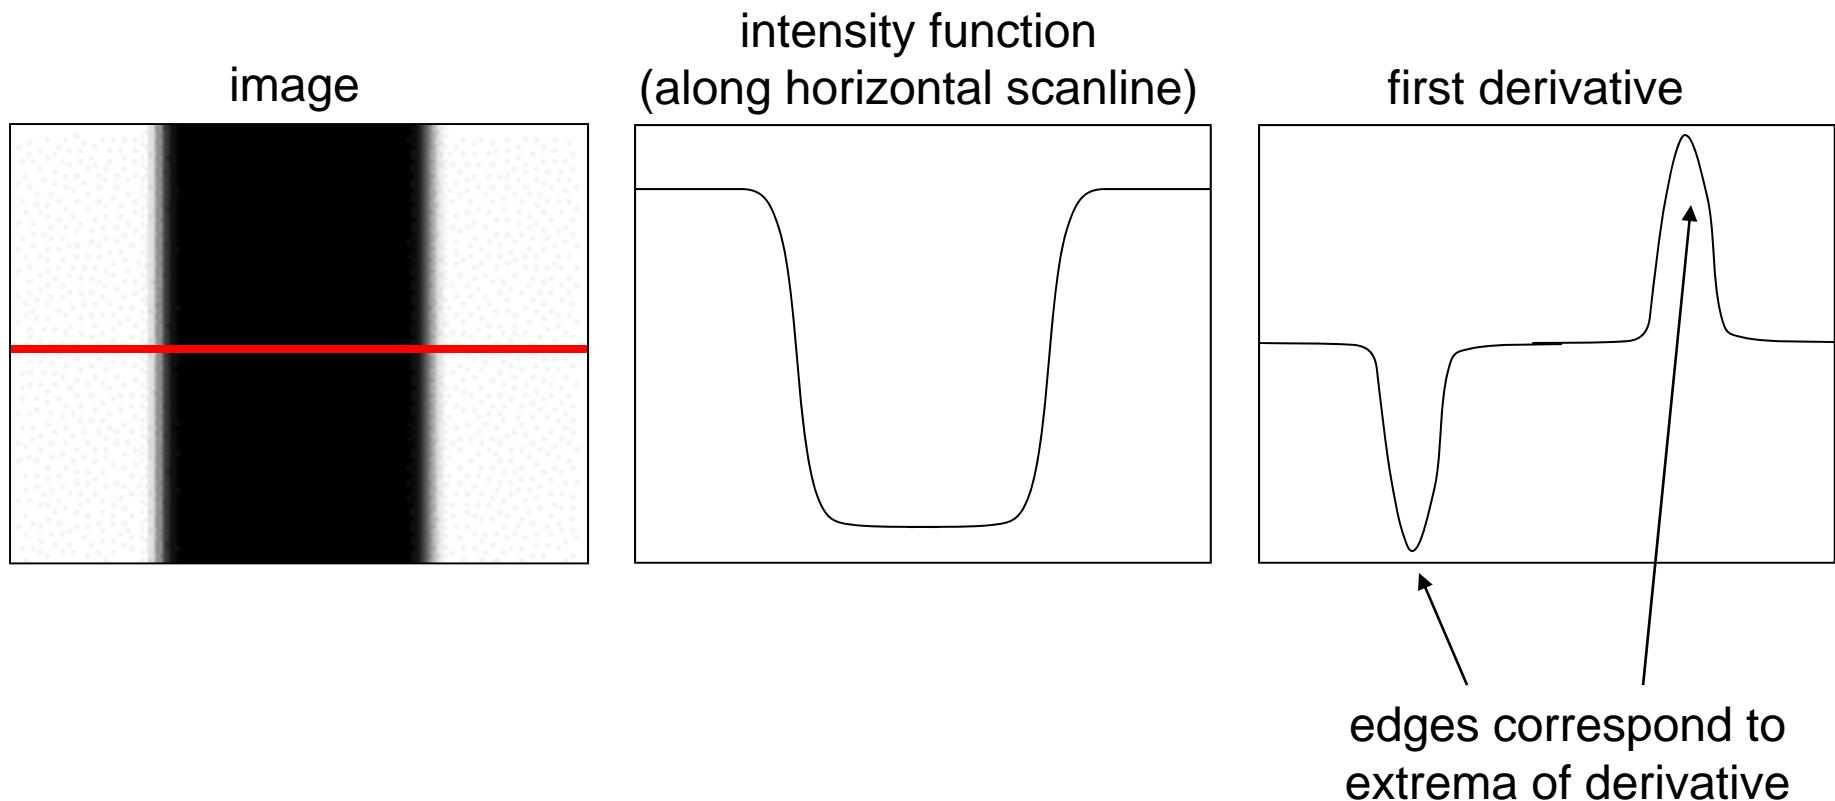

Source: Steve Seitz

# What we will learn today

- Edge detection
  - Canny edge detector
- Line fitting
  - Hough Transform
  - RANSAC

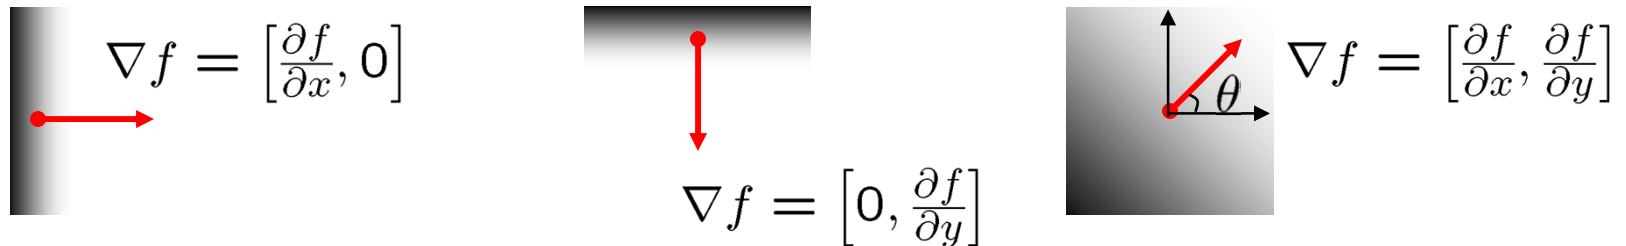

# Characterizing edges

- An edge is a place of rapid change in the image intensity function

# Image gradient

- The gradient of an image:  $\nabla f = \left[ \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right]$

The gradient points in the direction of most rapid increase in intensity

The gradient direction is given by  $\theta = \tan^{-1} \left( \frac{\partial f}{\partial y} / \frac{\partial f}{\partial x} \right)$

- how does this relate to the direction of the edge?

The *edge strength* is given by the gradient magnitude

$$\|\nabla f\| = \sqrt{\left(\frac{\partial f}{\partial x}\right)^2 + \left(\frac{\partial f}{\partial y}\right)^2}$$

Source: Steve Seitz

# Differentiation and convolution

- Recall, for 2D function,  $f(x,y)$ :

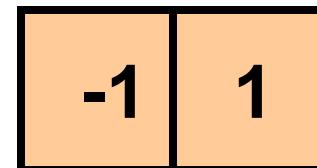

$$\frac{\partial f}{\partial x} = \lim_{\varepsilon \rightarrow 0} \left( \frac{f(x + \varepsilon, y) - f(x, y)}{\varepsilon} \right)$$

- We could approximate this as

$$\frac{\partial f}{\partial x} \approx \frac{f(x_{n+1}, y) - f(x_n, y)}{\Delta x}$$

- This is linear and shift invariant, so must be the result of a convolution.

- (which is obviously a convolution)

Source: D. Forsyth, D. Lowe

# Finite difference filters

- Other approximations of derivative filters

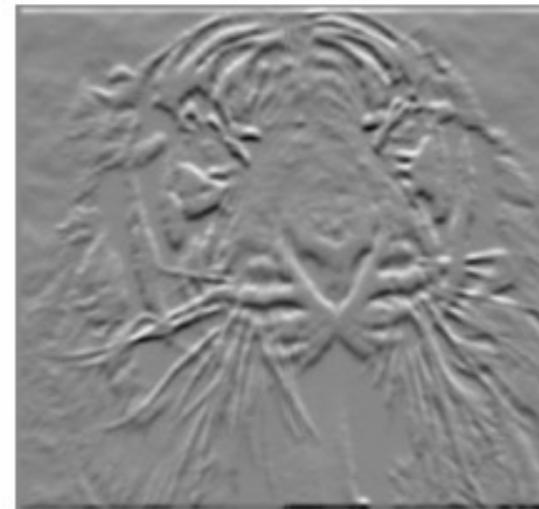

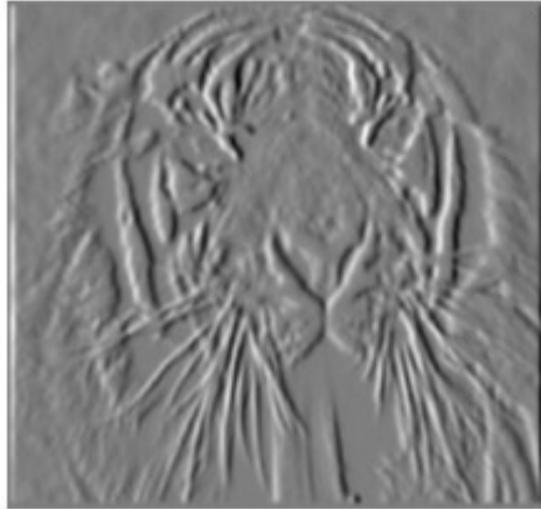

**Prewitt:**  $M_x = \begin{bmatrix} -1 & 0 & 1 \\ -1 & 0 & 1 \\ -1 & 0 & 1 \end{bmatrix}$  ;  $M_y = \begin{bmatrix} 1 & 1 & 1 \\ 0 & 0 & 0 \\ -1 & -1 & -1 \end{bmatrix}$

**Sobel:**  $M_x = \begin{bmatrix} -1 & 0 & 1 \\ -2 & 0 & 2 \\ -1 & 0 & 1 \end{bmatrix}$  ;  $M_y = \begin{bmatrix} 1 & 2 & 1 \\ 0 & 0 & 0 \\ -1 & -2 & -1 \end{bmatrix}$

**Roberts:**  $M_x = \begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}$  ;  $M_y = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$

Source: K. Grauman

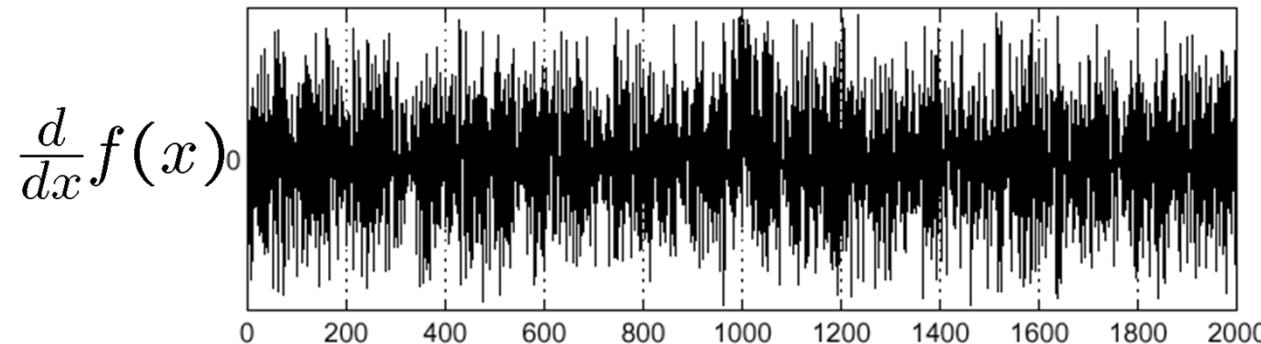

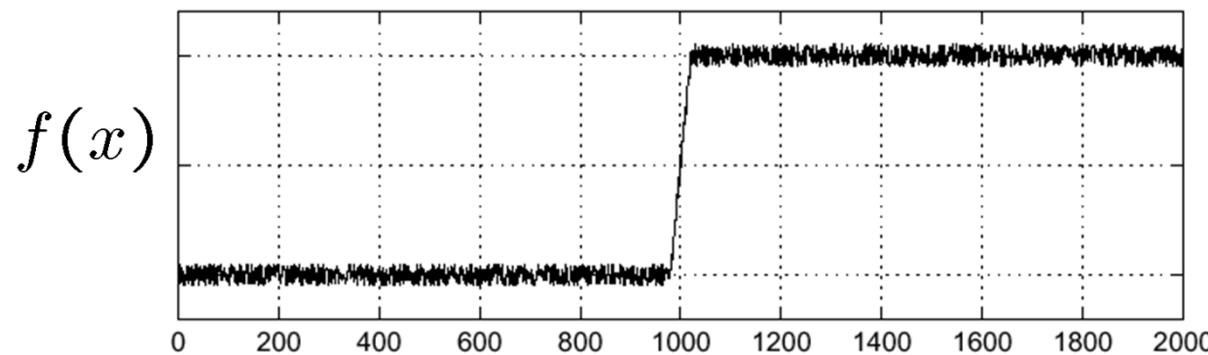

# Finite differences: example

- Which one is the gradient in the x-direction? How about y-direction?

# Effects of noise

- Consider a single row or column of the image
  - Plotting intensity as a function of position gives a signal

Where is the edge?

Source: S. Seitz

# Effects of noise

- Finite difference filters respond strongly to noise
  - Image noise results in pixels that look very different from their neighbors
  - Generally, the larger the noise the stronger the response
- What is to be done?

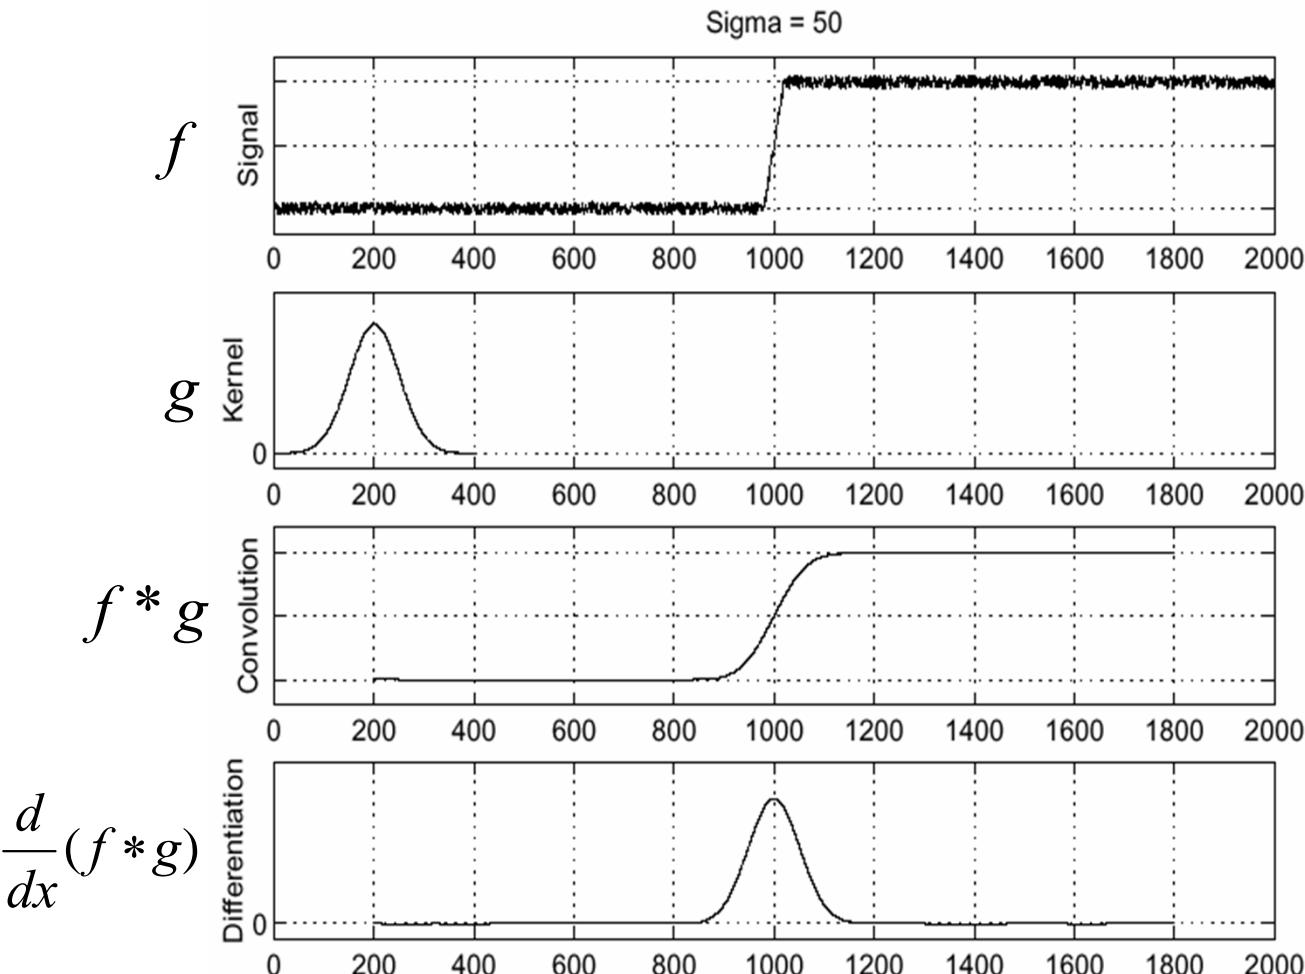

Source: D. Forsyth

# Effects of noise

- Finite difference filters respond strongly to noise
  - Image noise results in pixels that look very different from their neighbors
  - Generally, the larger the noise the stronger the response
- What is to be done?
  - Smoothing the image should help, by forcing pixels different to their neighbors (=noise pixels?) to look more like neighbors

Source: D. Forsyth

# Solution: smooth first

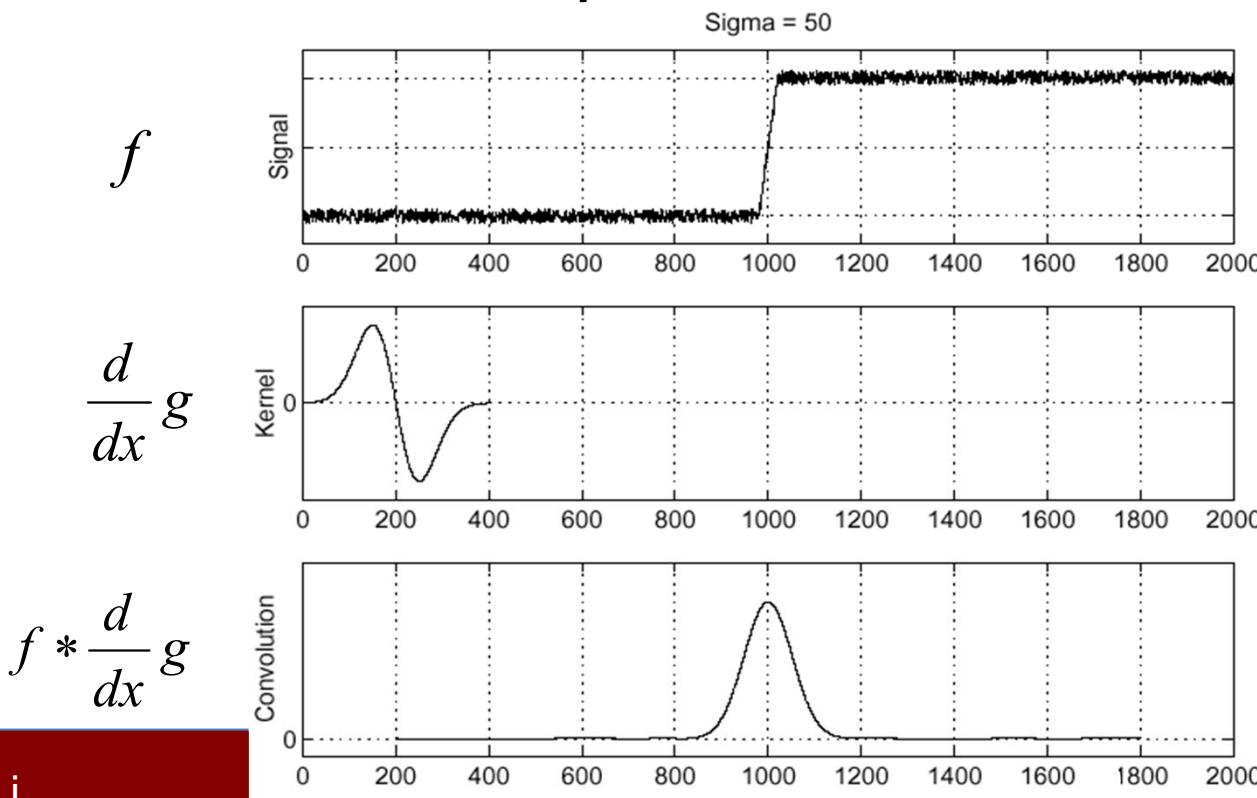

- To find edges, look for peaks in

$$\frac{d}{dx}(f * g)$$

Source: S. Seitz

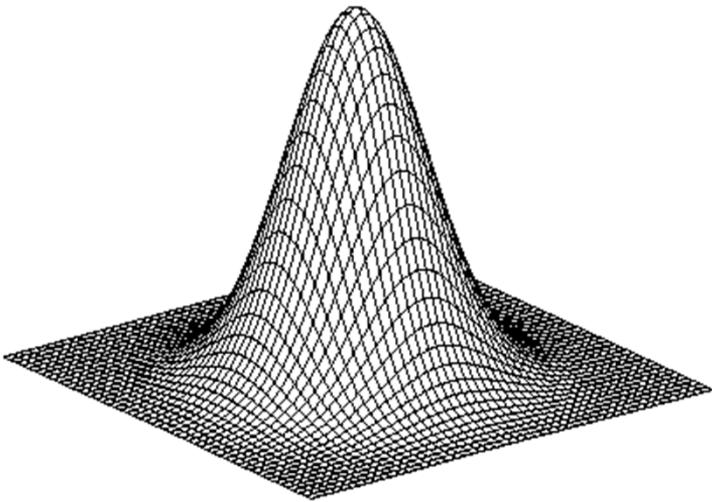

# Derivative theorem of convolution

- Differentiation is convolution, and convolution is associative:  
$$\frac{d}{dx}(f * g) = f * \frac{d}{dx}g$$
- This saves us one operation:

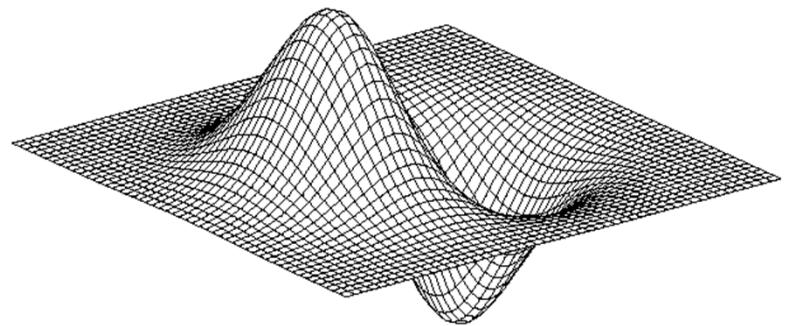

Source: S. Seitz

# Derivative of Gaussian filter

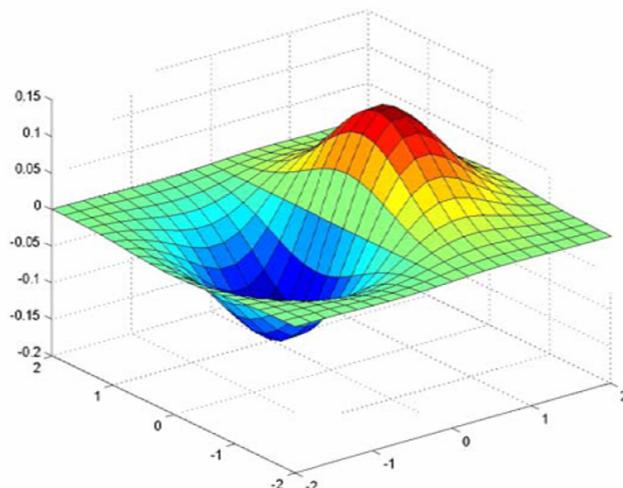

$$* [1 \ -1] =$$

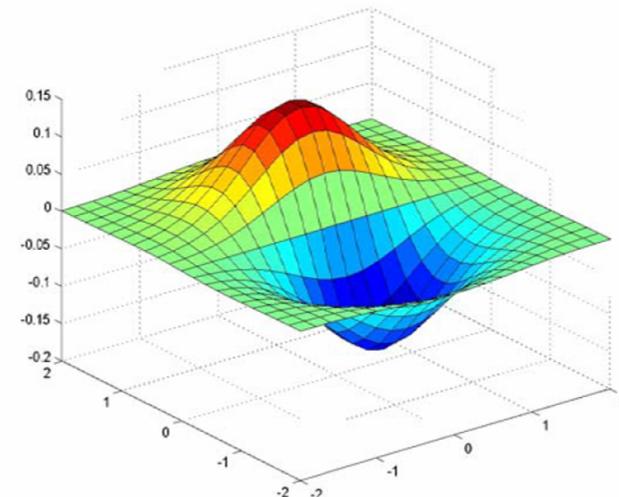

- Is this filter separable?

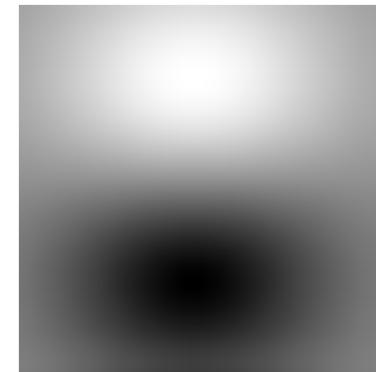

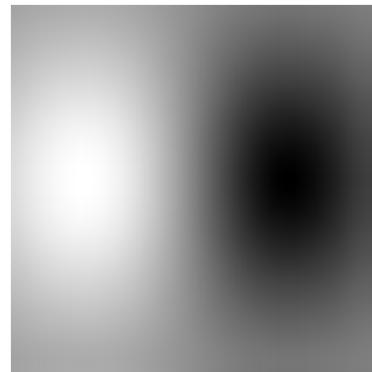

# Derivative of Gaussian filter

x-direction

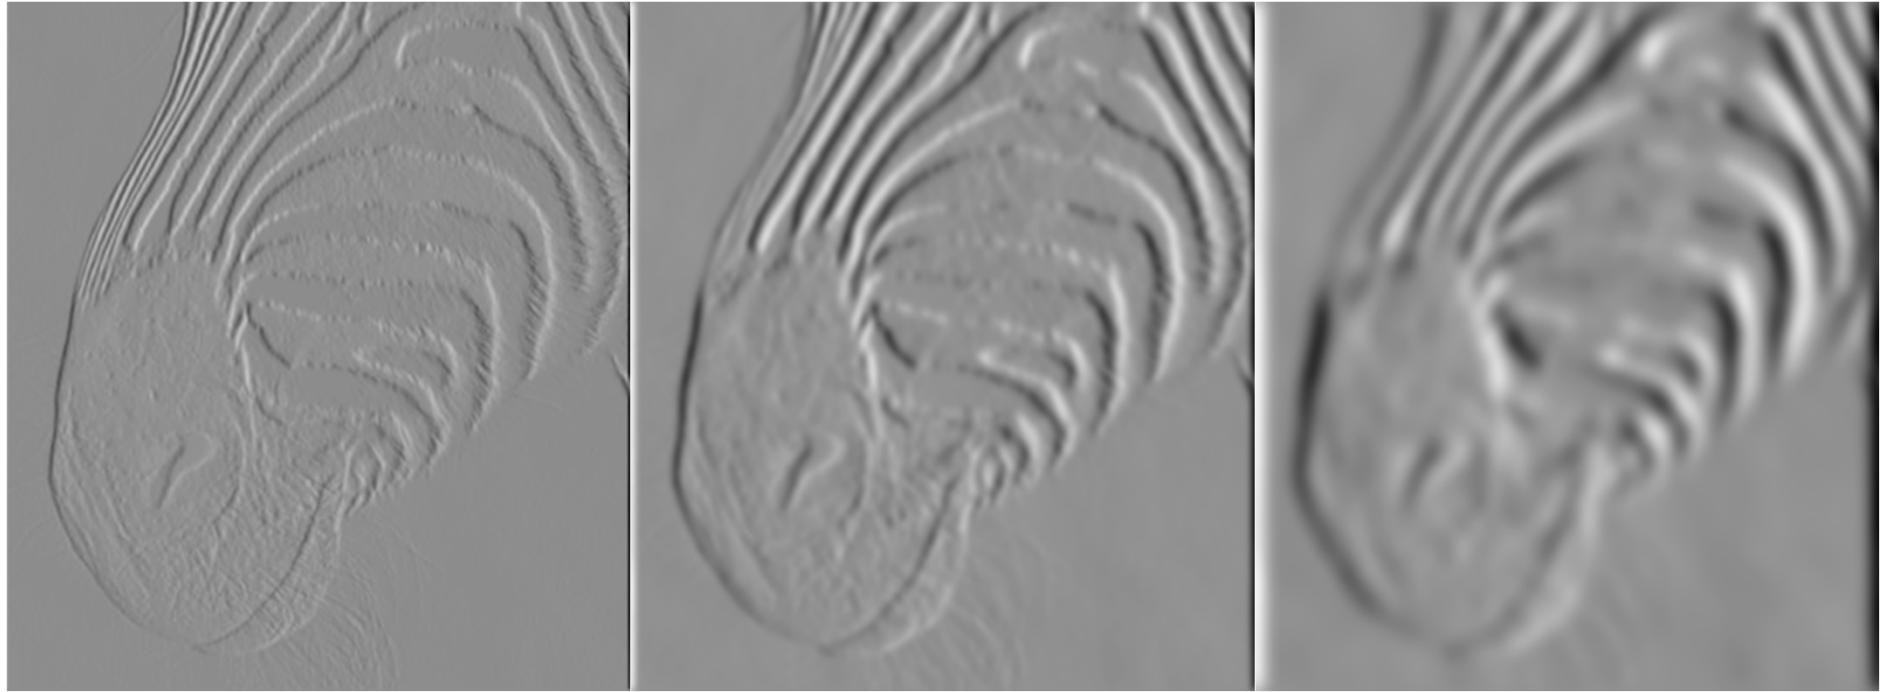

y-direction

- Which one finds horizontal/vertical edges?

# Tradeoff between smoothing and localization

1 pixel

3 pixels

7 pixels

- Smoothed derivative removes noise, but blurs edge. Also finds edges at different “scales”.

Source: D. Forsyth

# Implementation issues

- The gradient magnitude is large along a thick “trail” or “ridge,” so how do we identify the actual edge points?
- How do we link the edge points to form curves?

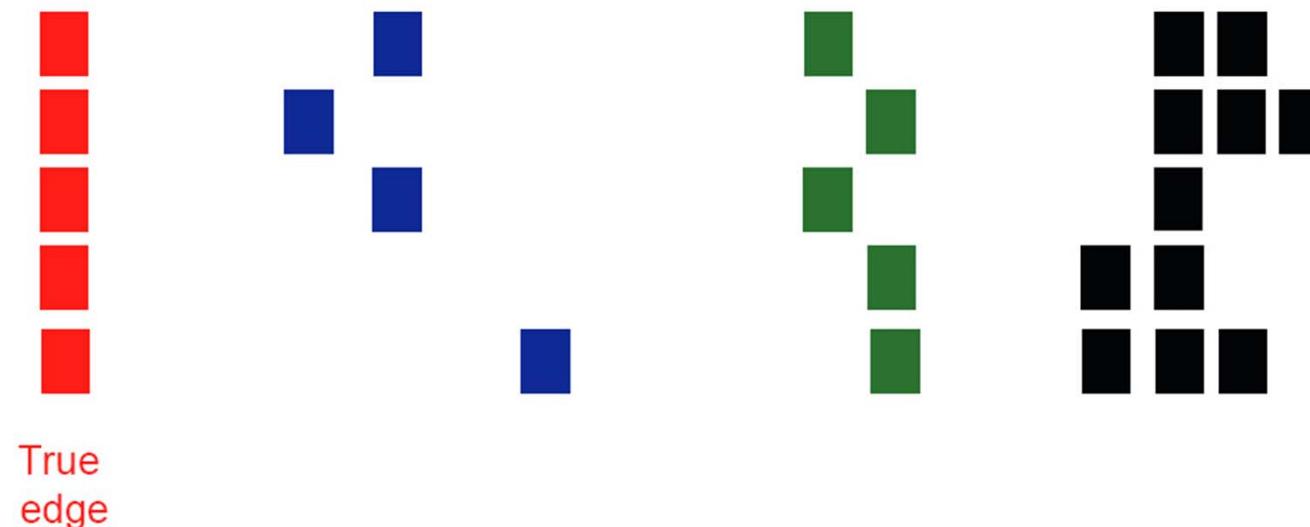

Source: D. Forsyth

# Designing an edge detector

- Criteria for an “optimal” edge detector:
  - **Good detection:** the optimal detector must minimize the probability of false positives (detecting spurious edges caused by noise), as well as that of false negatives (missing real edges)
  - **Good localization:** the edges detected must be as close as possible to the true edges
  - **Single response:** the detector must return one point only for each true edge point; that is, minimize the number of local maxima around the true edge

# Designing an edge detector

- Criteria for an “optimal” edge detector:
  - Good detection
  - Good localization
  - Single response

# Canny edge detector

- This is probably the most widely used edge detector in computer vision
- Theoretical model: step-edges corrupted by additive Gaussian noise
- Canny has shown that the first derivative of the Gaussian closely approximates the operator that optimizes the product of *signal-to-noise ratio* and localization

J. Canny, [A Computational Approach To Edge Detection](#), IEEE Trans. Pattern Analysis and Machine Intelligence, 8:679-714, 1986.

# Canny edge detector

1. Filter image with derivative of Gaussian
  2. Find magnitude and orientation of gradient
  3. Non-maximum suppression:
    - Thin multi-pixel wide “ridges” down to single pixel width
  4. Linking and thresholding (hysteresis):
    - Define two thresholds: low and high
    - Use the high threshold to start edge curves and the low threshold to continue them
- 
- MATLAB: `edge(image, 'canny')`

# Example

- original image (Lena)

# Example

norm of the gradient

# Example

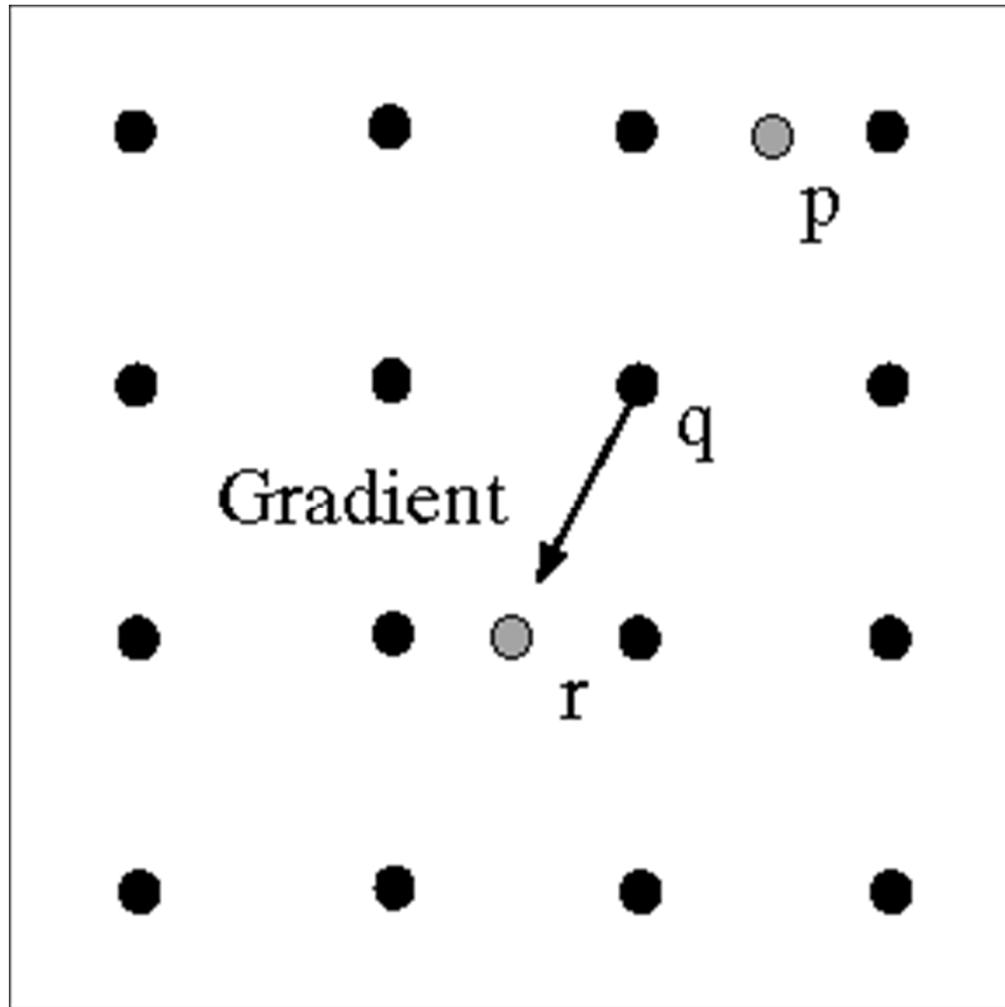

thresholding

# Example

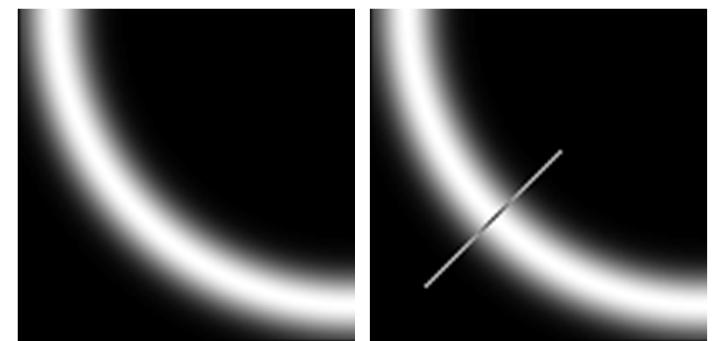

Thinning (non-maximum suppression)

# Non-maximum suppression

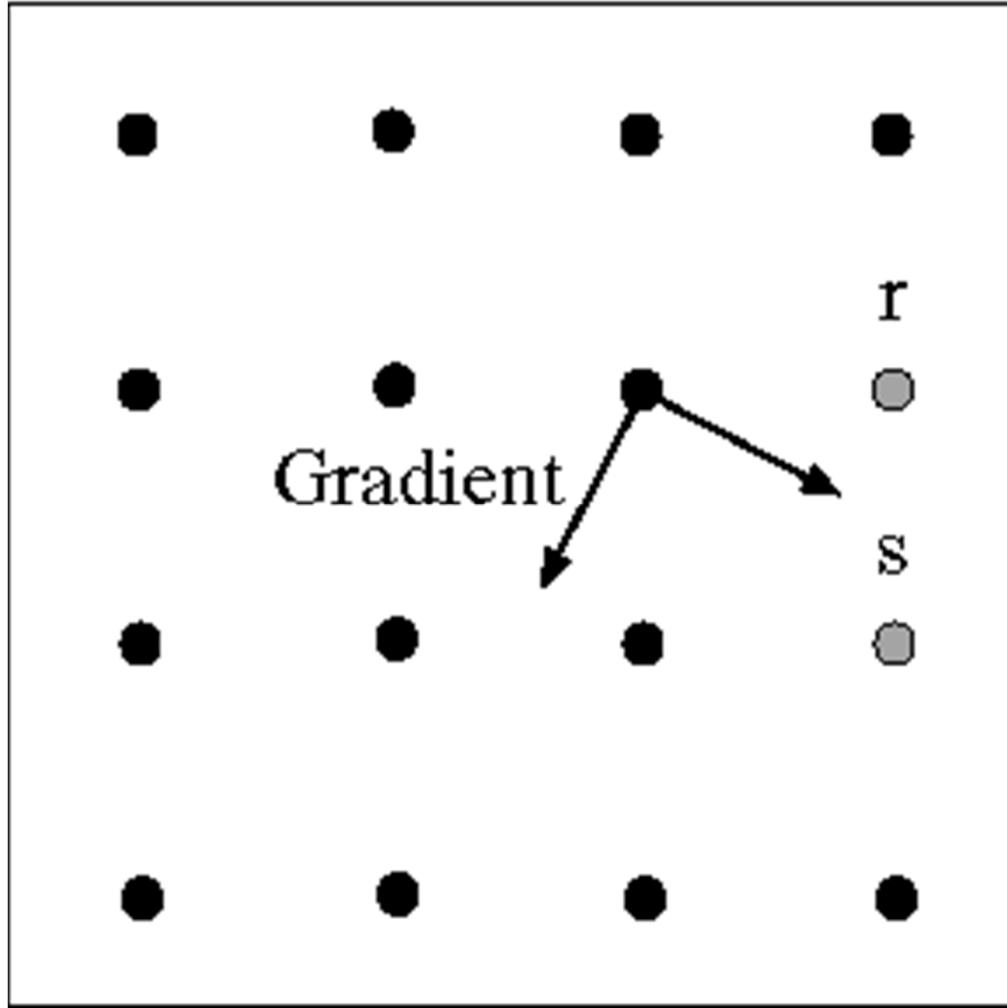

At q, we have a maximum if the value is larger than those at both p and at r.  
Interpolate to get these values.

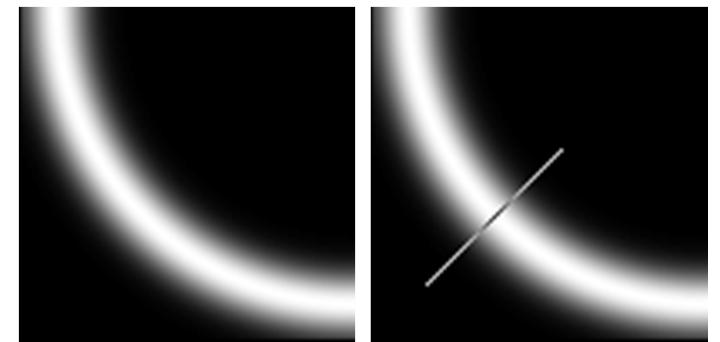

Source: D. Forsyth

# Edge linking

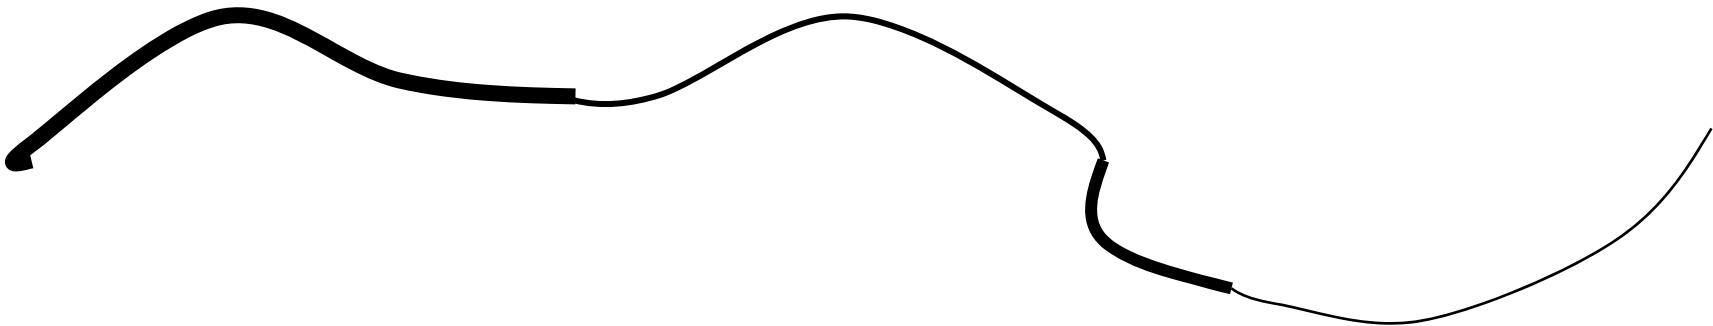

Assume the marked point is an edge point. Then we construct the tangent to the edge curve (which is normal to the gradient at that point) and use this to predict the next points (here either r or s).

Source: D. Forsyth

# Hysteresis thresholding

- Check that maximum value of gradient value is sufficiently large
  - drop-outs? use **hysteresis**
    - use a high threshold to start edge curves and a low threshold to continue them.

Source: S. Seitz

# Hysteresis thresholding

original image

high threshold  
(strong edges)

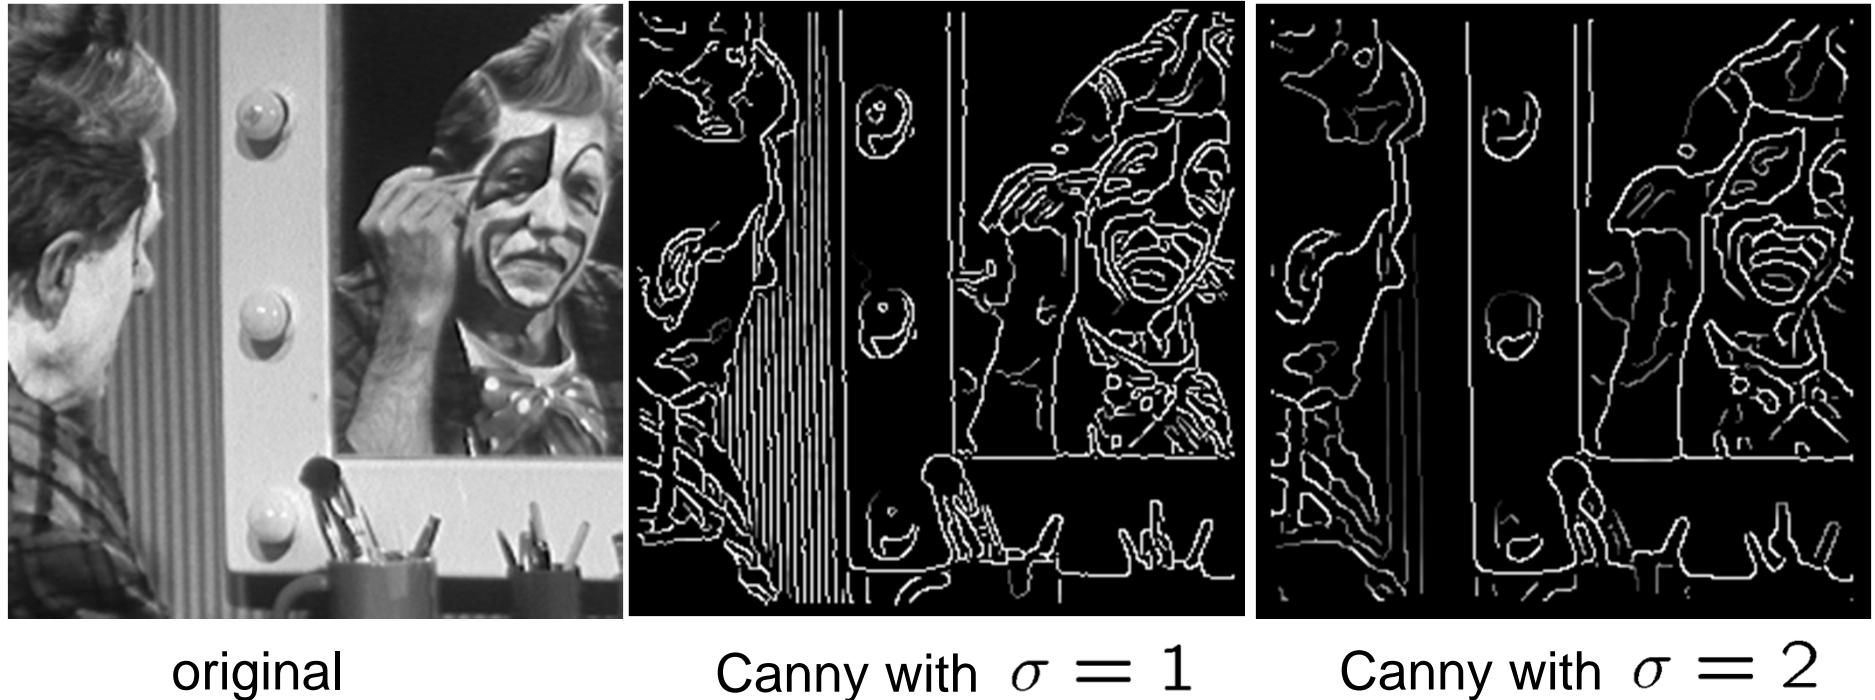

low threshold  
(weak edges)

hysteresis threshold

# Effect of $\sigma$ (Gaussian kernel spread/size)

The choice of  $\sigma$  depends on desired behavior

- large  $\sigma$  detects large scale edges
- small  $\sigma$  detects fine features

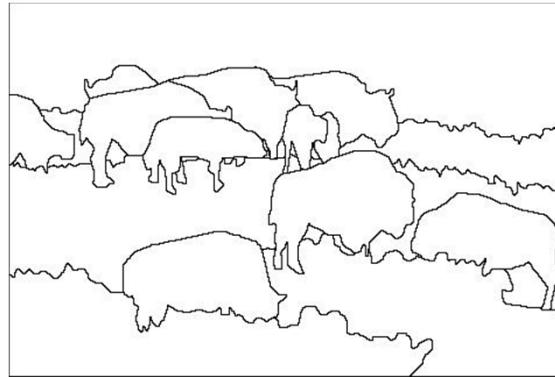

Source: S. Seitz

# Edge detection is just the beginning...

<http://www.eecs.berkeley.edu/Research/Projects/CS/vision/grouping/segbench/>

# What we will learn today

- Edge detection
  - Canny edge detector
- Line fitting
  - Hough Transform
  - RANSAC (**Problem Set 2 (Q5)**)

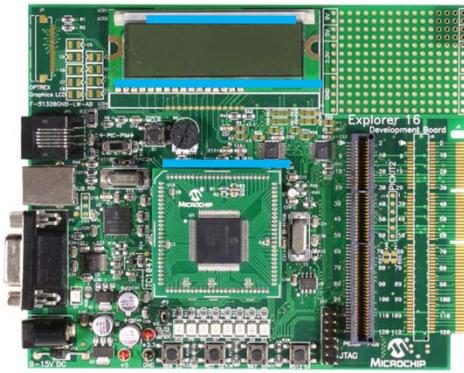

# Fitting as Search in Parametric Space

- Choose a parametric model to represent a set of features
- Membership criterion is not local
  - Can't tell whether a point belongs to a given model just by looking at that point.
- Three main questions:
  - What model represents this set of features best?
  - Which of several model instances gets which feature?
  - How many model instances are there?
- Computational complexity is important
  - It is infeasible to examine every possible set of parameters and every possible combination of features

Source: L. Lazebnik

# Example: Line Fitting

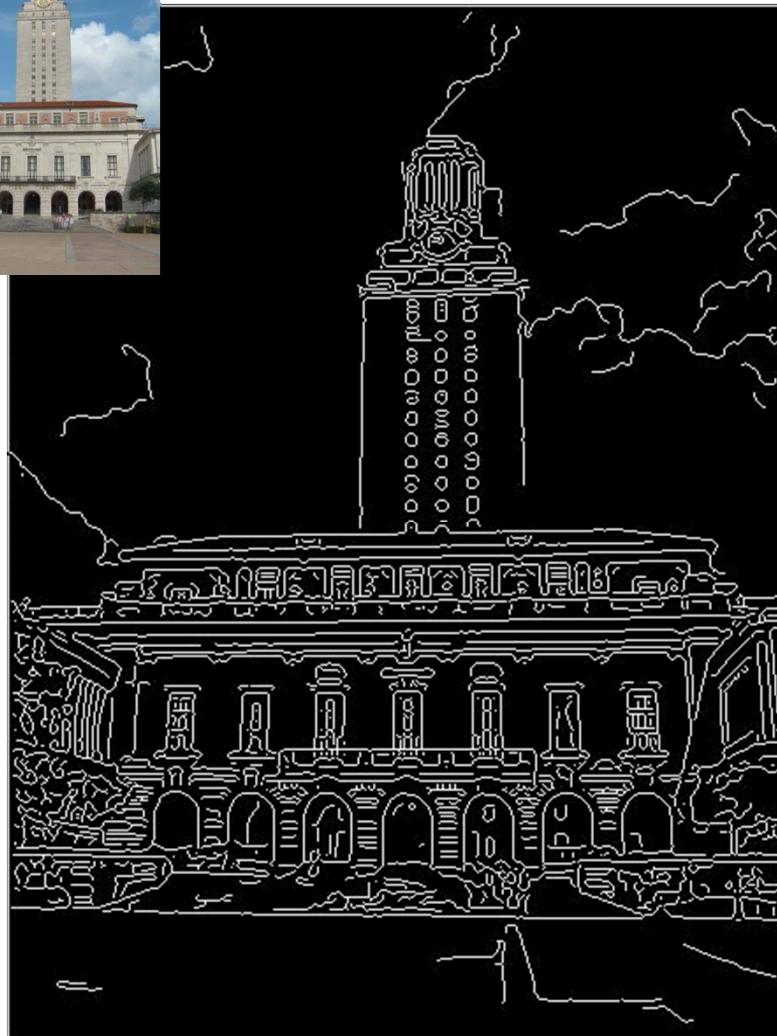

- Why fit lines?  
Many objects characterized by presence of straight lines

- Wait, why aren't we done just by running edge detection?

Slide credit: Kristen Grauman

# Difficulty of Line Fitting.

- Extra edge points (clutter), multiple models:
  - Which points go with which line, if any?
- Only some parts of each line detected, and some parts are missing:
  - How to find a line that bridges missing evidence?
- Noise in measured edge points, orientations:
  - How to detect true underlying parameters?

Slide credit: Kristen Grauman

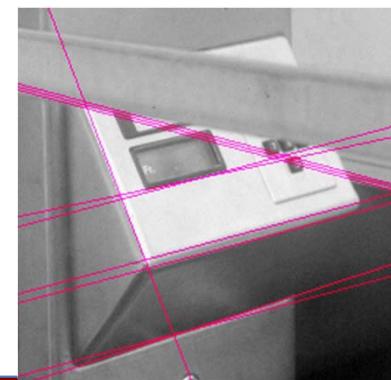

# Voting

- It's not feasible to check all combinations of features by fitting a model to each possible subset.
- Voting is a general technique where we let the features vote for all models that are compatible with it.
  - Cycle through features, cast votes for model parameters.
  - Look for model parameters that receive a lot of votes.
- Noise & clutter features will cast votes too, *but* typically their votes should be inconsistent with the majority of “good” features.
- Ok if some features not observed, as model can span multiple fragments.

Slide credit: Kristen Grauman

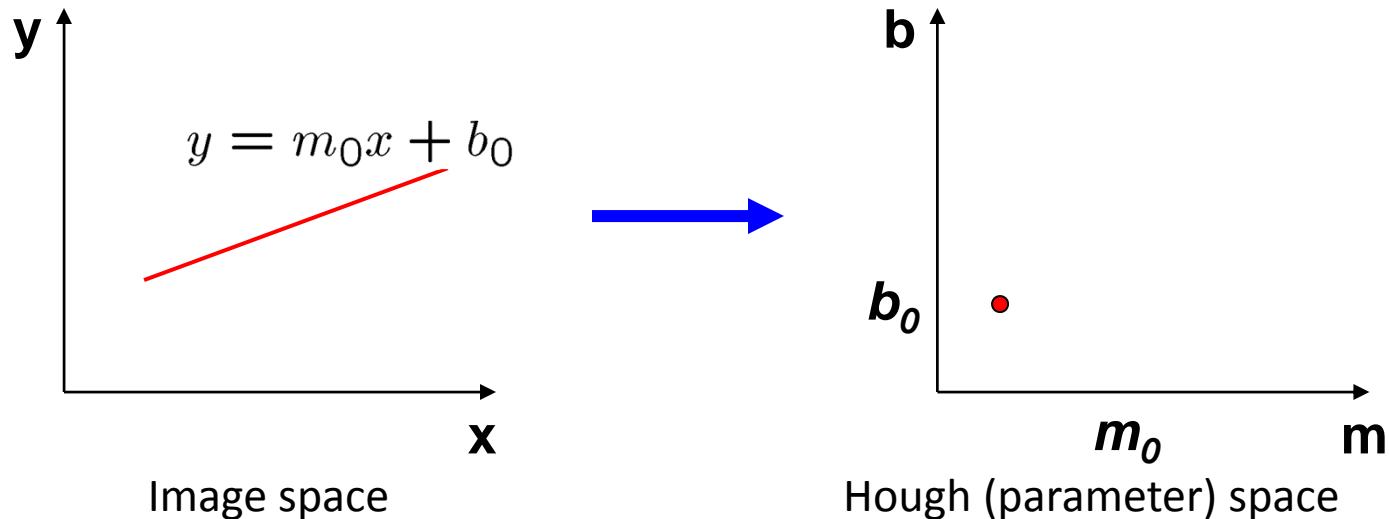

# Fitting Lines

- Given points that belong to a line, what is the line?
  - How many lines are there?
  - Which points belong to which lines?
- 
- *Hough Transform* is a voting technique that can be used to answer all of these
  - Main idea:
    1. Record all possible lines on which each edge point lies.
    2. Look for lines that get many votes.

Slide credit: Kristen Grauman

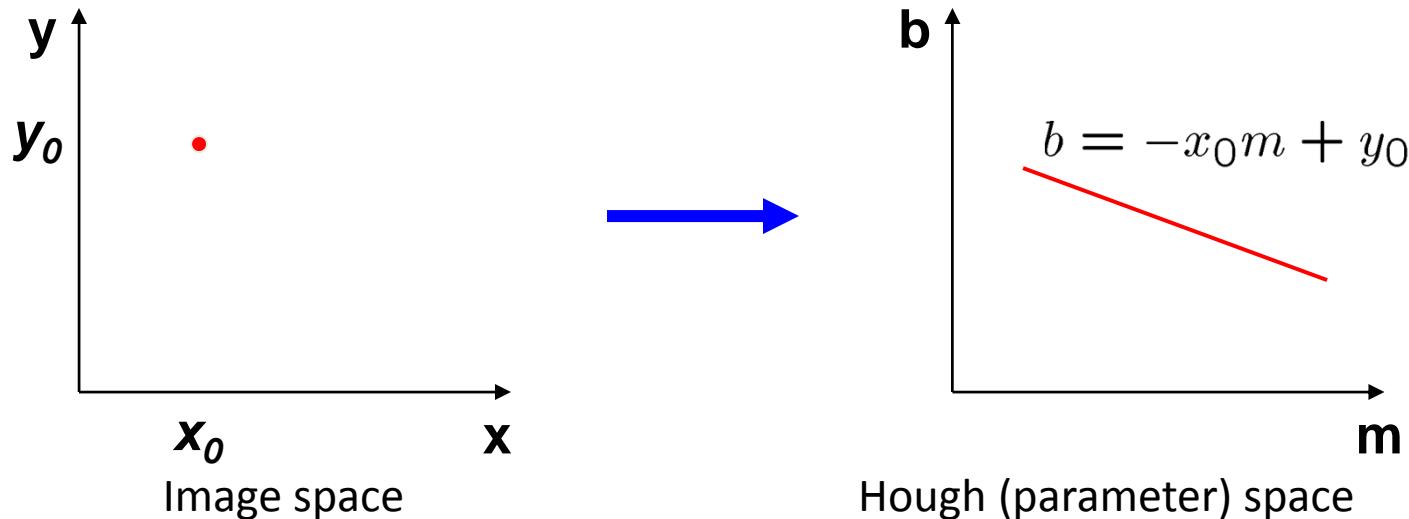

# Finding Lines in an Image: Hough Space

- Connection between image  $(x,y)$  and Hough  $(m,b)$  spaces
  - A line in the image corresponds to a point in Hough space.
  - To go from image space to Hough space:
    - Given a set of points  $(x,y)$ , find all  $(m,b)$  such that  $y = mx + b$

Slide credit: Steve Seitz

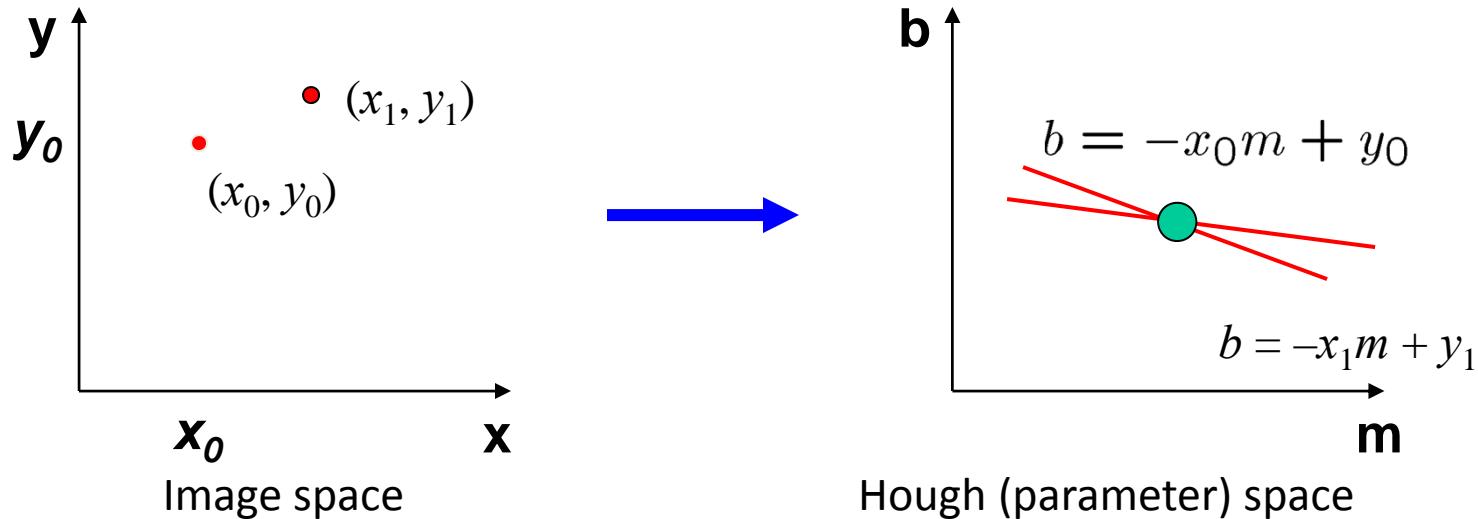

# Finding Lines in an Image: Hough Space

- Connection between image  $(x,y)$  and Hough  $(m,b)$  spaces
  - A line in the image corresponds to a point in Hough space.
  - To go from image space to Hough space:
    - Given a set of points  $(x,y)$ , find all  $(m,b)$  such that  $y = mx + b$
  - What does a point  $(x_0, y_0)$  in the image space map to?
    - Answer: the solutions of  $b = -x_0 m + y_0$
    - This is a line in Hough space

Slide credit: Steve Seitz

# Finding Lines in an Image: Hough Space

- What are the line parameters for the line that contains both  $(x_0, y_0)$  and  $(x_1, y_1)$ ?
  - It is the intersection of the lines  $b = -x_0m + y_0$  and  $b = -x_1m + y_1$

Slide credit: Steve Seitz

# Finding Lines in an Image: Hough Space

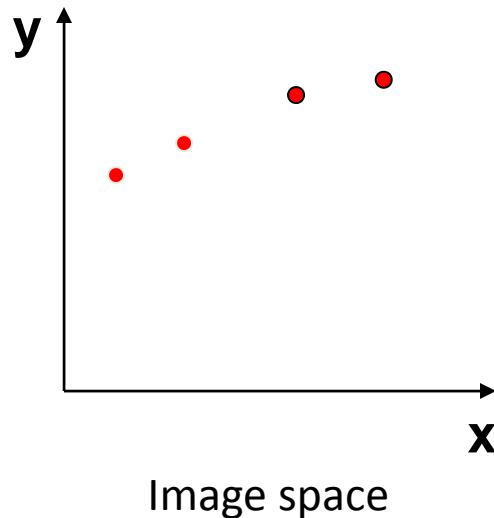

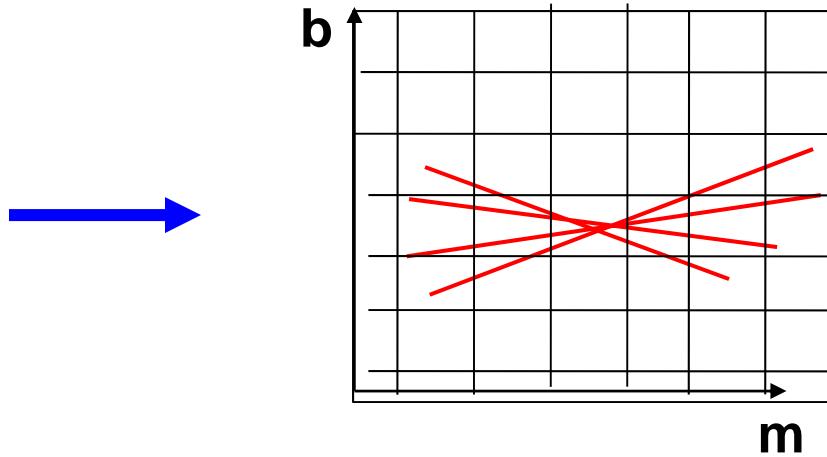

Image space

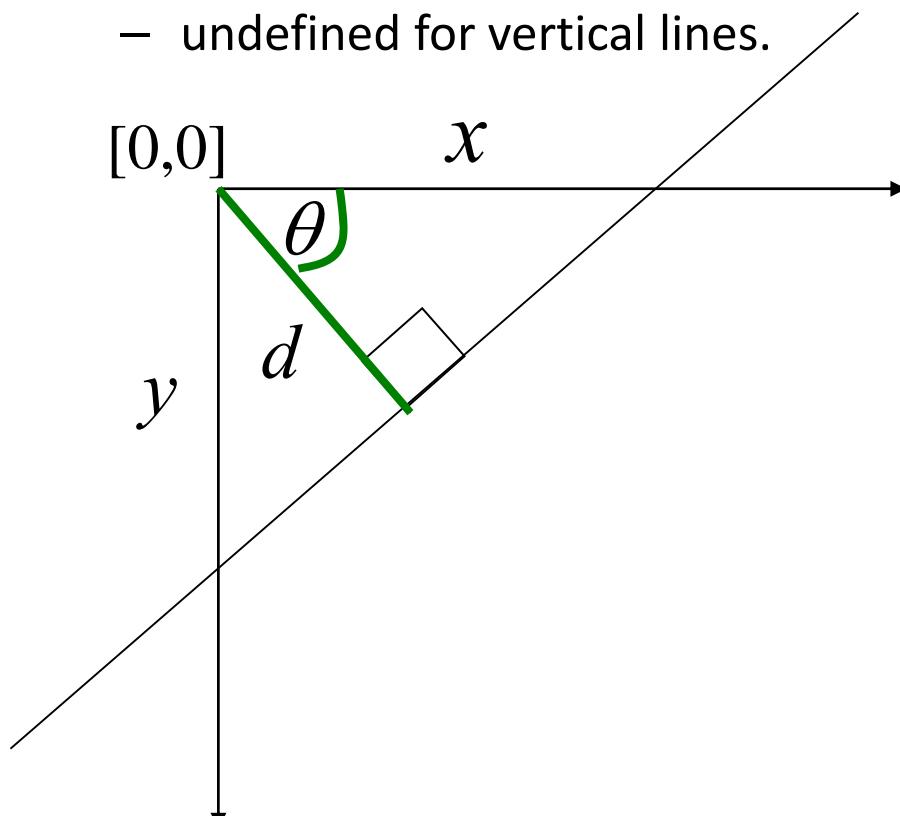

Hough (parameter) space

- How can we use this to find the most likely parameters  $(m, b)$  for the most prominent line in the image space?
  - Let each edge point in image space *vote* for a set of possible parameters in Hough space
  - Accumulate votes in discrete set of bins; parameters with the most votes indicate line in image space.

Slide credit: Steve Seitz

# Polar Representation for Lines

- Issues with usual  $(m, b)$  parameter space:
  - can take on infinite values;
  - undefined for vertical lines.

$d$  : perpendicular distance from line to origin

$\theta$  : angle the perpendicular line makes with the x-axis

$$x \cos \theta + y \sin \theta = d$$

where  $\theta \in [0, \pi)$  and  $d \in \mathbb{R}$

- Point in image space  $\Rightarrow$  sinusoid segment in Hough space

# Hough Transform Algorithm

Using the polar parameterization:

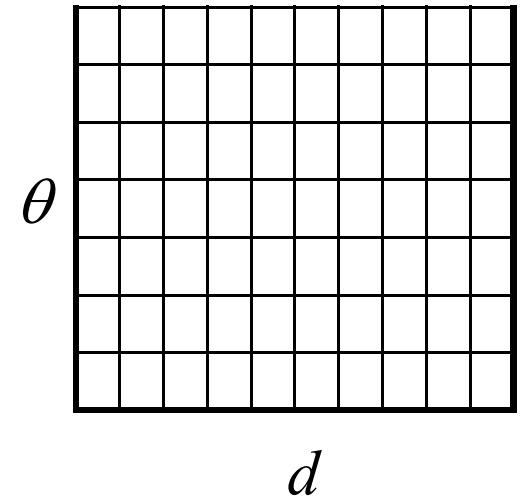

$$x \cos \theta + y \sin \theta = d$$

Basic Hough transform algorithm

1. Initialize  $H[d, \theta] = 0$ .
  2. For each edge point  $(x, y)$  in the image  
for  $\theta \in [0, \pi)$  // some quantization  
 $H[d, \theta] += 1$
  3. Find the value(s) of  $(d, \theta)$  where  $H[d, \theta]$  is maximum.
  4. The detected line in the image is given by  
$$d = x \cos \theta + y \sin \theta$$
- Time complexity (in terms of number of votes)?

[Hough line demo](#)

$H$ : accumulator array (votes)

# Generalized Hough Transform

- What if want to detect arbitrary shapes defined by boundary points and a reference point?

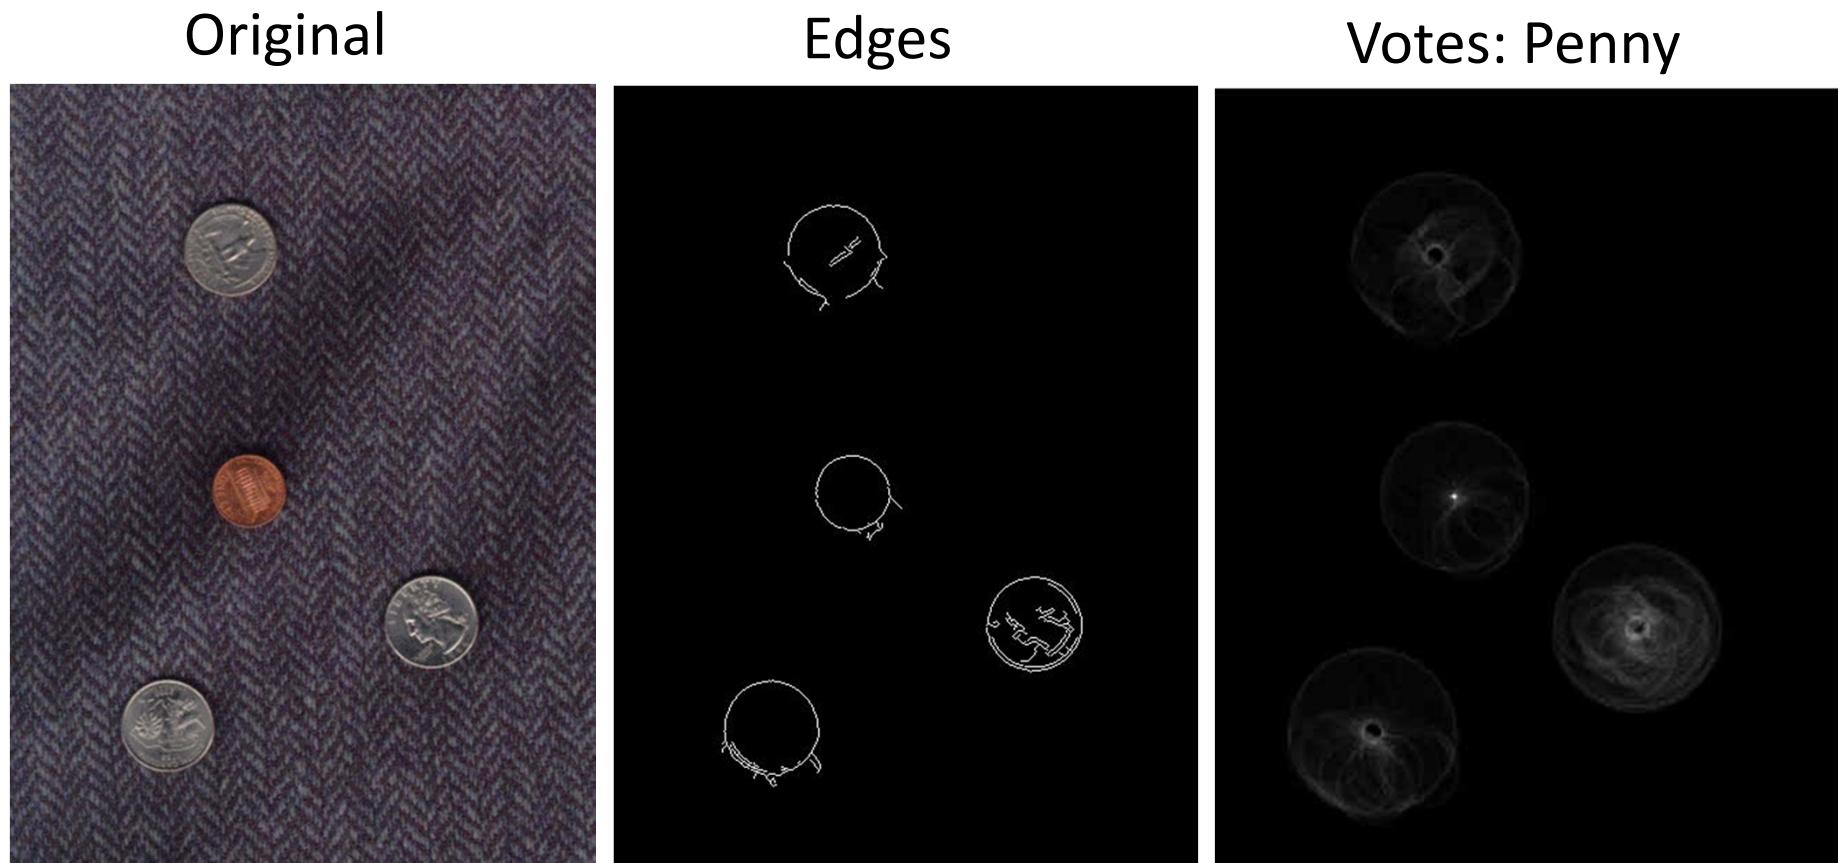

At each boundary point,  
compute displacement  
vector:  $r = a - p_i$ .

For a given model shape:  
store these vectors in a  
table indexed by gradient  
orientation  $\theta$ .

[Dana H. Ballard, Generalizing the Hough Transform to Detect Arbitrary Shapes, 1980]

# Example: Detecting Circles with Hough

Note: a different Hough transform (with separate accumulators) was used for each circle radius (quarters vs. penny).

# Voting: Practical Tips

- Minimize irrelevant tokens first (take edge points with significant gradient magnitude)
- Choose a good grid / discretization
  - Too coarse: large votes obtained when too many different lines correspond to a single bucket
  - Too fine: miss lines because some points that are not exactly collinear cast votes for different buckets
- Vote for neighbors, also (smoothing in accumulator array)
- Utilize direction of edge to reduce free parameters by 1
- To read back which points voted for “winning” peaks, keep tags on the votes.

Slide credit: Kristen Grauman

# Hough Transform: Pros and Cons

## Pros

- All points are processed independently, so can cope with occlusion
- Some robustness to noise: noise points unlikely to contribute consistently to any single bin
- Can detect multiple instances of a model in a single pass

## Cons

- Complexity of search time increases exponentially with the number of model parameters
- Non-target shapes can produce spurious peaks in parameter space
- Quantization: hard to pick a good grid size

Slide credit: Kristen Grauman

# Another model fitting strategy:

## RANSAC [Fischler & Bolles 1981]

- RANdom SAmple Consensus
- Approach: we want to avoid the impact of outliers, so let's look for “inliers”, and use only those.
- Intuition: if an outlier is chosen to compute the current fit, then the resulting line won't have much support from rest of the points.

Slide credit: Kristen Grauman

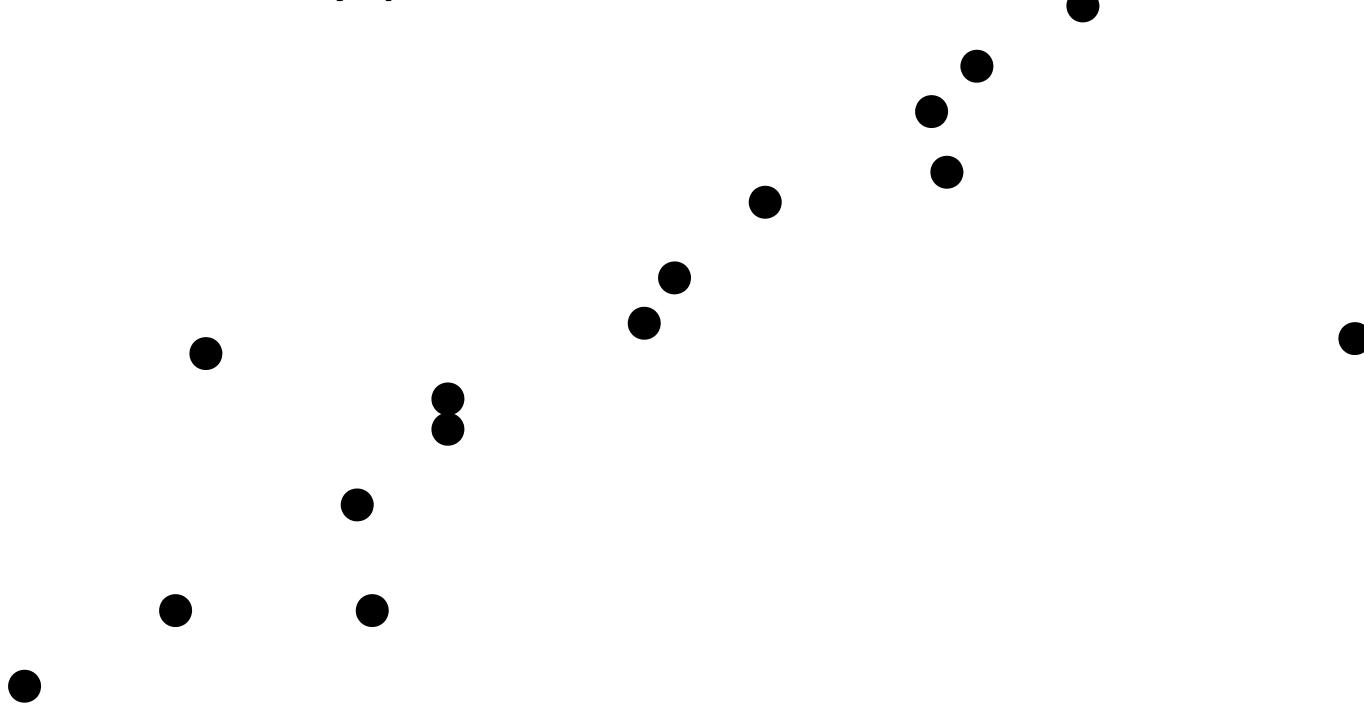

# RANSAC

## RANSAC loop:

1. Randomly select a *seed group* of points on which to base transformation estimate (e.g., a group of matches)
2. Compute transformation from seed group
3. Find *inliers* to this transformation
4. If the number of inliers is sufficiently large, re-compute least-squares estimate of transformation on all of the inliers
  - Keep the transformation with the largest number of inliers

# RANSAC Line Fitting Example

#### Algorithm 15.4: RANSAC: fitting lines using random sample consensus

Determine:

$n$  — the smallest number of points required

$k$  — the number of iterations required

$t$  — the threshold used to identify a point that fits well

$d$  — the number of nearby points required  
to assert a model fits well

Until  $k$  iterations have occurred

    Draw a sample of  $n$  points from the data  
        uniformly and at random

    Fit to that set of  $n$  points

    For each data point outside the sample

        Test the distance from the point to the line  
            against  $t$ ; if the distance from the point to the line  
            is less than  $t$ , the point is close

    end

    If there are  $d$  or more points close to the line

        then there is a good fit. Refit the line using all  
        these points.

end

    Use the best fit from this collection, using the  
        fitting error as a criterion

# RANSAC: How many samples?

- How many samples are needed?
  - Suppose  $w$  is fraction of inliers (points from line).
  - $n$  points needed to define hypothesis (2 for lines)
  - $k$  samples chosen.
- Prob. that a single sample of  $n$  points is correct:  $w^n$
- Prob. that all  $k$  samples fail is:  $(1-w^n)^k$

⇒ Choose  $k$  high enough to keep this below desired failure rate.

Slide credit: David Lowe

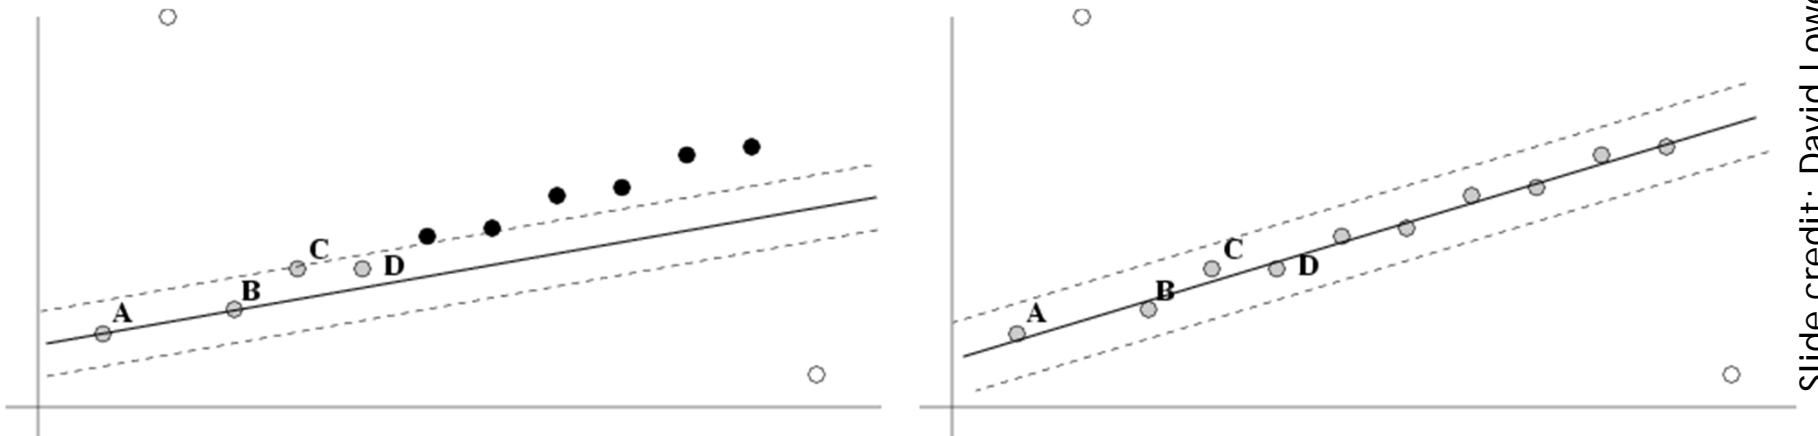

# RANSAC: Computed k (p=0.99)

Sample size <i>n</i>	Proportion of outliers						
	5%	10%	20%	25%	30%	40%	50%
2	2	3	5	6	7	11	17
3	3	4	7	9	11	19	35
4	3	5	9	13	17	34	72
5	4	6	12	17	26	57	146
6	4	7	16	24	37	97	293
7	4	8	20	33	54	163	588
8	5	9	26	44	78	272	1177

Slide credit: David Lowe

# After RANSAC

- RANSAC divides data into inliers and outliers and yields estimate computed from minimal set of inliers.
- Improve this initial estimate with estimation over all inliers (e.g. with standard least-squares minimization).
- But this may change inliers, so alternate fitting with re-classification as inlier/outlier.

Slide credit: David Lowe

# RANSAC: Pros and Cons

- **Pros:**
  - General method suited for a wide range of model fitting problems
  - Easy to implement and easy to calculate its failure rate
- **Cons:**
  - Only handles a moderate percentage of outliers without cost blowing up
  - Many real problems have high rate of outliers (but sometimes selective choice of random subsets can help)
- The Hough transform can handle high percentage of outliers

# What we have learned today

- Edge detection
  - Canny edge detector
- Line fitting
  - Hough Transform
  - RANSAC (**Problem Set 2 (Q5)**)

# Supplementary materials

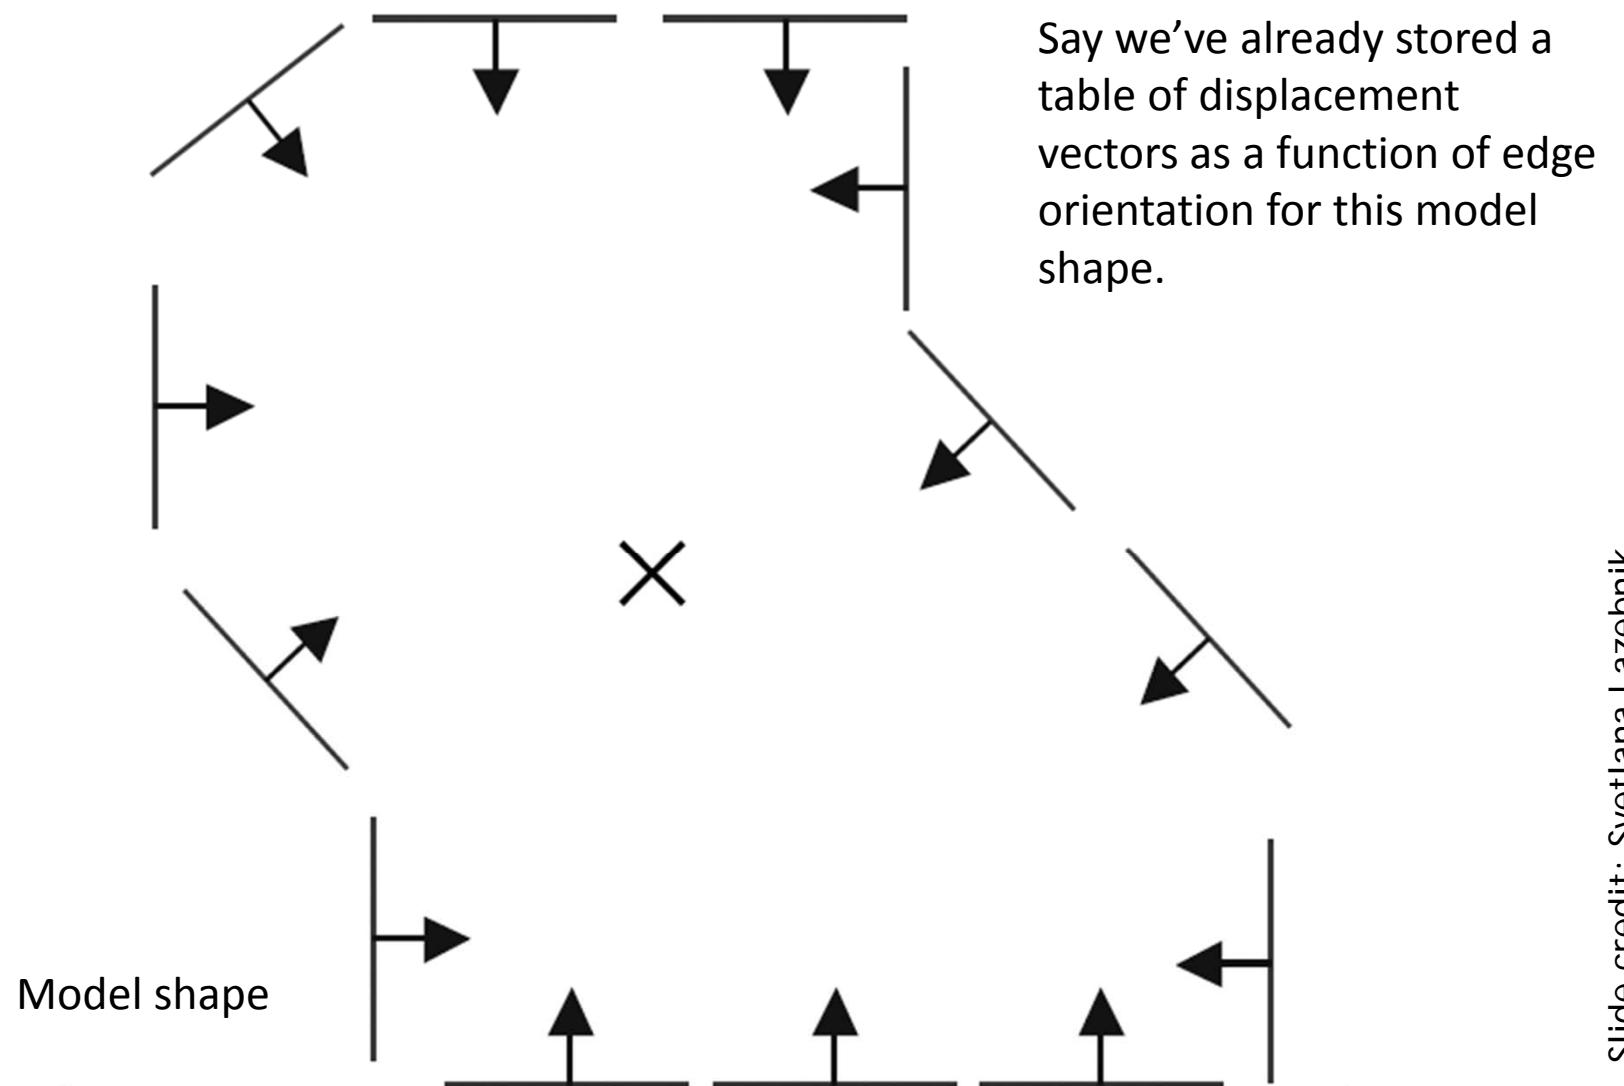

# Generalized Hough Transform

To *detect* the model shape in a new image:

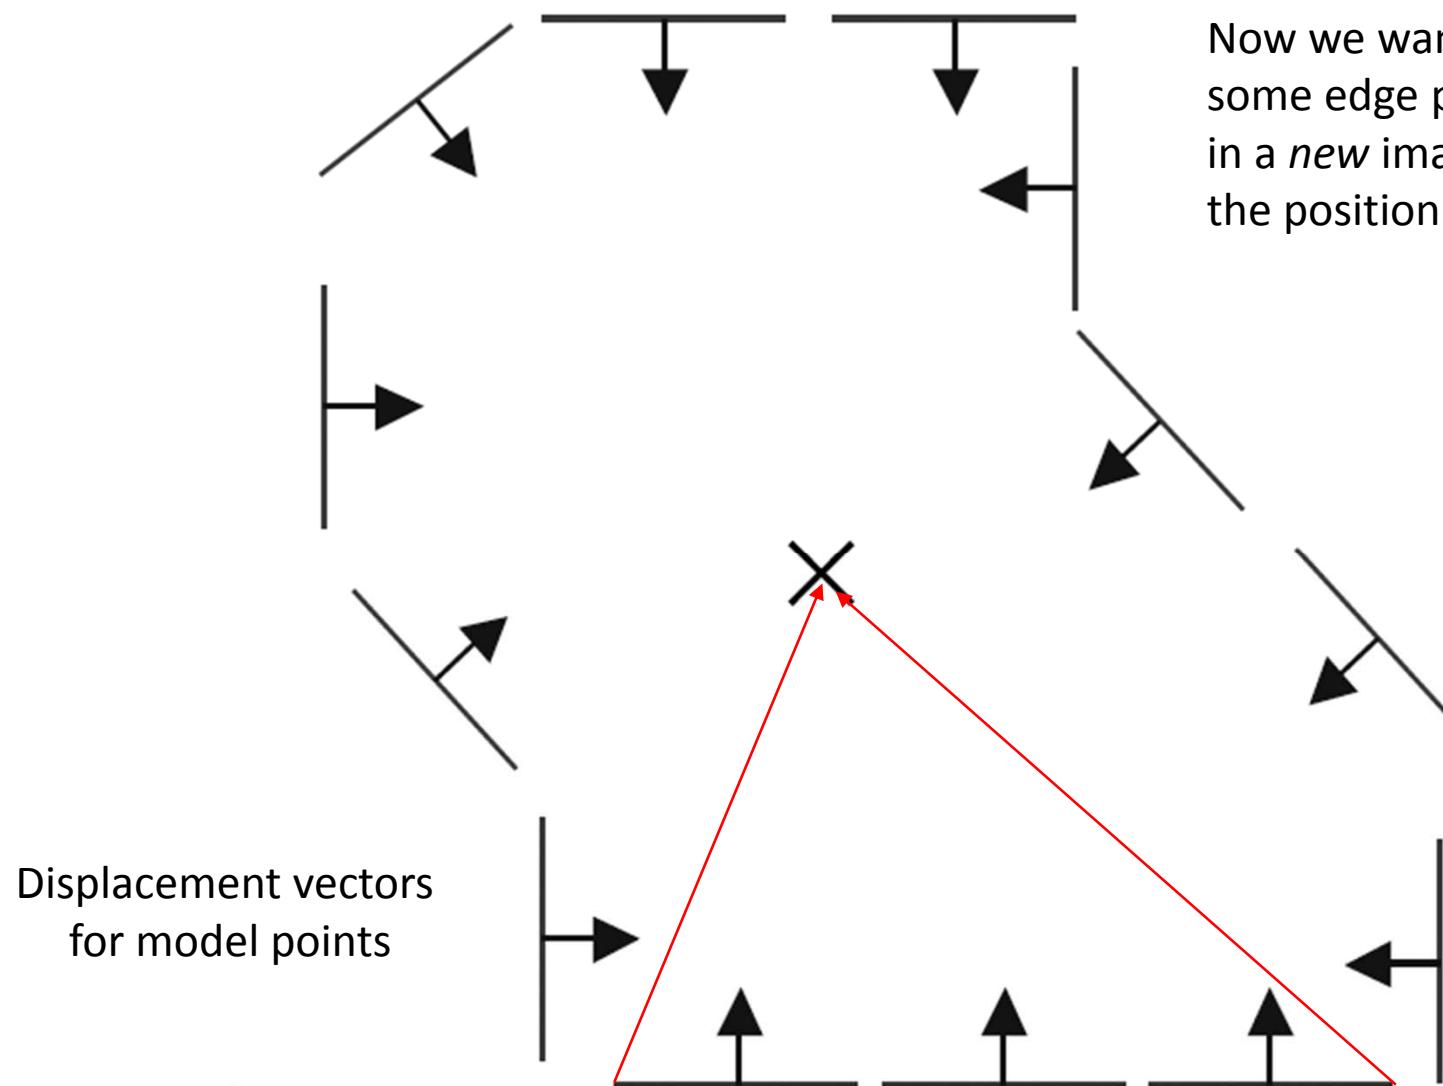

- For each edge point
  - Index into table with its gradient orientation  $\theta$
  - Use retrieved  $r$  vectors to vote for position of reference point
- Peak in this Hough space is reference point with most supporting edges

*Assuming translation is the only transformation here, i.e., orientation and scale are fixed.*

# Example: Generalized Hough Transform

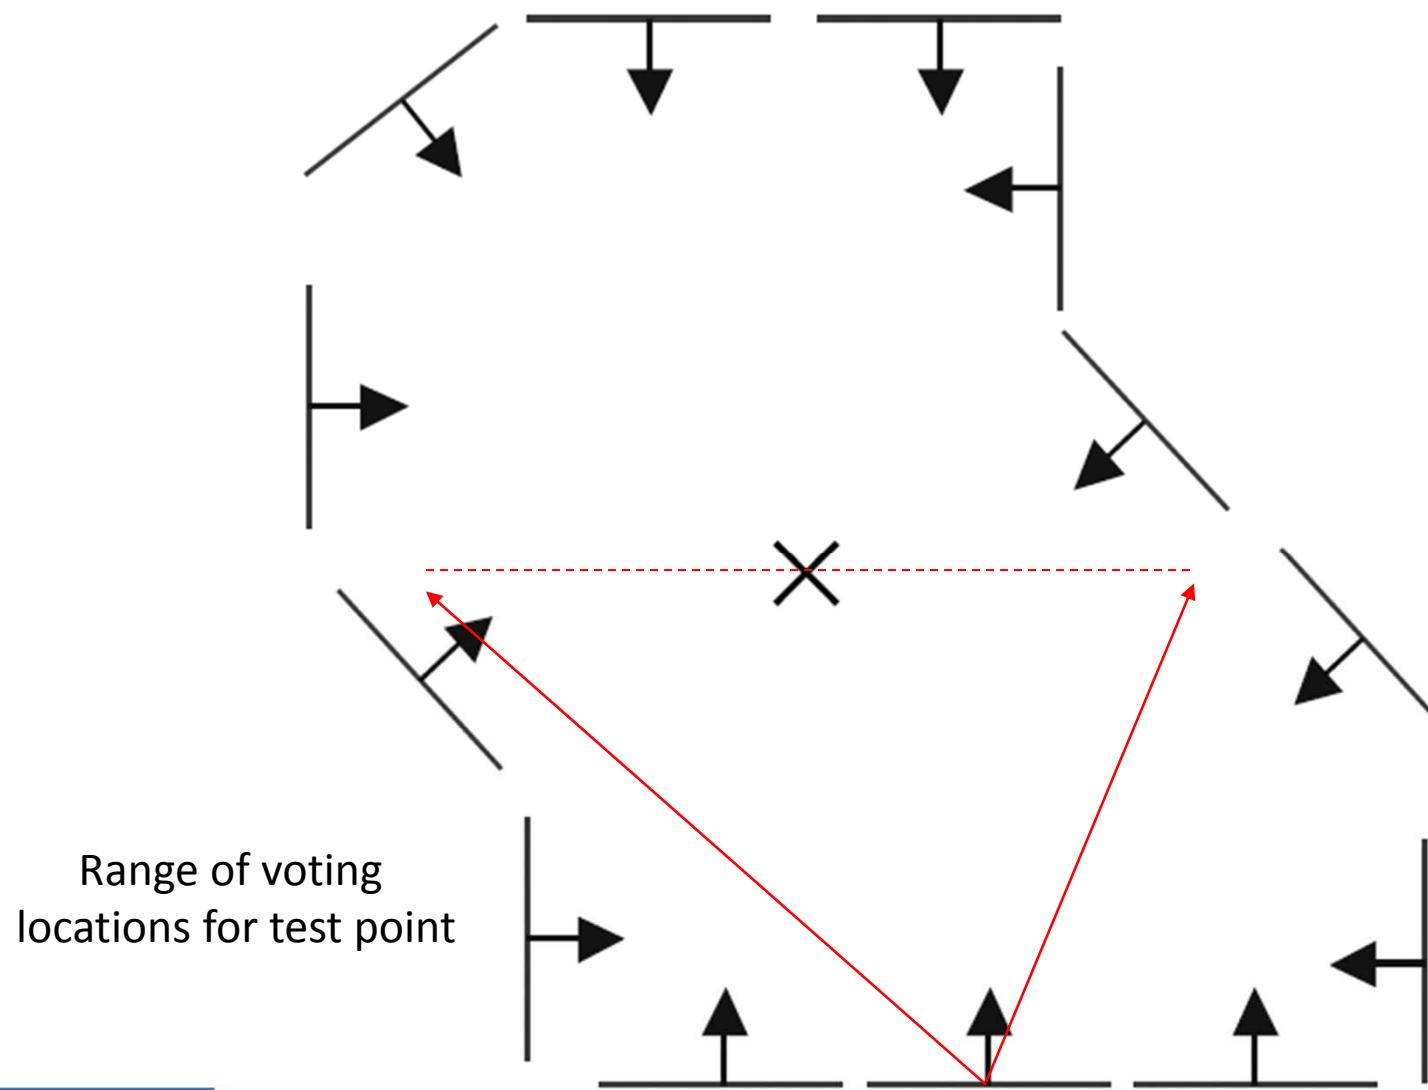

# Example: Generalized Hough Transform

# Example: Generalized Hough Transform

# Extensions to Hough Transform

# Extensions

Extension 1: Use the image gradient

1. same
2. for each edge point  $I[x,y]$  in the image

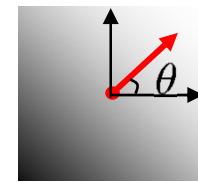

$\theta$ = gradient at  $(x,y)$

$$d = x \cos \theta - y \sin \theta$$

$$H[d, \theta] += 1$$

3. same
4. same

(Reduces degrees of freedom)

$$\nabla f = \left[ \frac{\partial f}{\partial x}, \frac{\partial f}{\partial y} \right]$$

$$\theta = \tan^{-1} \left( \frac{\partial f}{\partial y} / \frac{\partial f}{\partial x} \right)$$

# Extensions

## Extension 1: Use the image gradient

1. same
2. for each edge point  $I[x,y]$  in the image
  - compute unique  $(d,\theta)$  based on image gradient at  $(x,y)$
  - $H[d,\theta] += 1$
3. same
4. same

(Reduces degrees of freedom)

## Extension 2

- Give more votes for stronger edges (use magnitude of gradient)

## Extension 3

- Change the sampling of  $(d,\theta)$  to give more/less resolution

## Extension 4

- The same procedure can be used with circles, squares, or any other shape...

# Extension: Cascaded Hough Transform

- Let's go back to the original  $(m, b)$  parametrization
- A line in the image maps to a pencil of lines in the Hough space
- What do we get with parallel lines or a pencil of lines?
  - Collinear peaks in the Hough space!
- So we can apply a Hough transform to the output of the first Hough transform to find vanishing points
